## **SEATWORK 7.1 Data Wrangling and Notebook Demonstration**

Name: Calingo, Christian Lei S.

Section: CPE22S3

Course: Computational Thinking With Python

Course Code: CPE311

## 7.5 (HANDLING MISSING DATA)

## Setup

import pandas as pd
df = pd.read\_csv('data/dirty\_data.csv')

## Finding problematic data

df #as we look in the data, some of them are NaN Values and some are ? Values

	date	station	PRCP	SNOW	SNWD	TMAX	TMIN	TOBS	WESF	inclement_weather	
0	2018-01-01T00:00:00	?	0.0	0.0	-inf	5505.0	-40.0	NaN	NaN	NaN	th
1	2018-01-01T00:00:00	?	0.0	0.0	-inf	5505.0	-40.0	NaN	NaN	NaN	
2	2018-01-01T00:00:00	?	0.0	0.0	-inf	5505.0	-40.0	NaN	NaN	NaN

765 rc	765 rows × 10 columns										

Looking at summary statistics can reveal strange or missing values:

df.describe()

/usr/local/lib/python3.10/dist-packages/numpy/lib/function\_base.py:4655: RuntimeWarning: invalid value encountered in subtract diff\_b\_a = subtract(b, a)

### Using info() function, we can pinpoint the missing values and incorrect data types

```
df.info() # The number under the non-null count shows us how many rows doesn't have NaN values with accordance of its column
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 765 entries, 0 to 764
Data columns (total 10 columns):
                    Non-Null Count Dtype
# Column
                     765 non-null

9 inclement_weather 408 non-null
                                    object
dtypes: float64(7), object(3)
memory usage: 59.9+ KB
```

### With the use of pd.isnull() / pd.isna() or the isna() / isnull(), we can find nulls

```
contain_nulls = df[
df.SNOW.isnull() | df.SNWD.isna()\
| pd.isnull(df.TOBS) | pd.isna(df.WESF)\
| df.inclement_weather.isna()
]
contain_nulls.shape

# if we remove the index in .shape(), we can see a tuple
# the index[0] is the number of nulls while the inde[1] is the number of columns

(765, 10)
```

contain\_nulls.head(10)

	date	station	PRCP	SNOW	SNWD	TMAX	TMIN	TOBS	WESF	inclement_weather

6	2018-01-03T00:00:00	GHCND:USC00280907	0.0	0.0	-inf	-4.4	-13.9	-13.3	NaN	False
7	2018-01-04T00:00:00	?	20.6	229.0	inf	5505.0	-40.0	NaN	19.3	True
8	2018-01-04T00:00:00	?	20.6	229.0	inf	5505.0	-40.0	NaN	19.3	True
9	2018-01-05T00:00:00	?	0.3	NaN	NaN	5505.0	-40.0	NaN	NaN	NaN

#### We can't check if we have NaN like this

```
df[df.inclement_weather == 'NaN'].shape[0]
0
```

### This is because it is actually np.nan . However, notice this also doesn't work

```
import numpy as np
df[df.inclement_weather == np.nan].shape[0]
0
```

#### We have to use one of the methods discussed earlier for this to work

#### We can find -inf / inf by comparing to -np.inf / np.inf

```
df[df.SNWD.isin([-np.inf, np.inf])].shape[0]
577
```

### Rather than do this for each column, we can write a function that will use a dictionary comprehension to check all the columns for us:

```
import numpy as np
def get_inf_count(df):
    return {
    col : df[df[col].isin([np.inf, -np.inf])].shape[0] for col in df.columns
    }
    get_inf_count(df)

    {'date': 0,
        'station': 0,
        'PRCP': 0,
        'SNOW': 0,
        'SNOW': 0,
        'NMIN': 0,
        'TMAX': 0,
        'TMIN': 0,
        'TOBS': 0,
        'WESF': 0,
        'inclement_weather': 0}
```

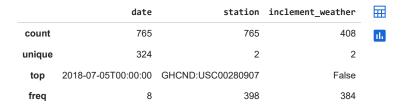

Before we can decide how to handle the infinite values of snow depth, we should look at the summary statistics for snowfall which form a big part in determining the snow depth

```
pd.DataFrame({
  'np.inf Snow Depth': df[df.SNWD == np.inf].SNOW.describe(),
  '-np.inf Snow Depth': df[df.SNWD == -np.inf].SNOW.describe()
}).T
```

```
\blacksquare
                   count
                                mean
                                             std
                                                  min
                                                        25%
                                                               50%
                                                                      75%
                                                                             max
np.inf Snow Depth
                    24.0 101.041667 74.498018 13.0 25.0 120.5 152.0 229.0
                                                                                    ıl.
-np.inf Snow Depth 553.0
                            0.000000
                                       0.000000
                                                  0.0
                                                         0.0
                                                               0.0
                                                                      0.0
                                                                             0.0
```

Let's now look into the date and station columns. We saw the ? for station earlier, so we know that was the other unique value. However, we see that some dates are present 8 times in the data and we only have 324 days meaning we are also missing days

```
df.describe(include='object')
```

#### We can use the duplicated() method to find duplicate rows

The default for keep is 'first' meaning it won't show the first row that the duplicated data was seen in; we can pass in False to see it though:

```
df[df.duplicated(keep=False)].shape[0]
482
```

#### We can also specify the columns to use:

```
df[df.duplicated(['date', 'station'])].shape[0]
284
```

#### Trying other columns

```
df[df.duplicated(['inclement_weather', 'PRCP'])].shape
  (636, 10)
```

Let's look at a few duplicates. Just in the few values we see here, we know that the top 4 are actually in the data 6 times because by default we aren't seeing their first occurrence:

```
df[df.duplicated()].head()
                                                                      TMAX TMIN TOBS WESF inclement_weather
                      date
                                         station PRCP
                                                         SNOW
                                                              SNWD
                                                                                                                   扁
      1 2018-01-01T00:00:00
                                               ?

                                                                 inf 5505.0 -40.0
                                                                                  NaN
                                                                                                            True
```

## Mitigating Issues

# Handling duplicated data

Since we know we have NY weather data and noticed we only had two entries for station, we may decide to drop the station column because we are only interested in the weather data. However, when dealing with duplicate data, we need to think of the ramifications of removing it.

Notice we only have data for the WESF column when the station is ?:

```
df[df.WESF.notna()].station.unique()
    array(['?'], dtype=object)
```

```
station_qm_wesf = df[df.station == '?'].WESF

df.sort_values('station', ascending=False, inplace=True)

df_deduped = df.drop_duplicates('date').drop(

columns=['station', 'WESF']
).sort_values('date').assign(

WESF=station_qm_wesf
)
df_deduped.shape

(324, 9)
```

### Check out the 4th row, we have WESF in the correct spot thanks to the index

```
df_deduped.head()
                        date PRCP
                                    SNOW SNWD
                                                  TMAX TMIN TOBS inclement_weather WESF
                                                                                                \blacksquare

                                            inf 5505.0 -40.0 NaN
                                                                                   True
                                                                                        19.3
      11 2018-01-05T00:00:00 14.2 127.0
                                                   -4.4 -13.9 -13.9
                                                                                   True
                                                                                        NaN
```

## Dealing with nulls

```
df_deduped.dropna().shape
    (0, 9)
```

### Using how = all, we can choose to only drop the rows where everything is null

### We can use just a subset of columns to determine what to drop with the subset argument

```
df_deduped.dropna(
how='all', subset=['inclement_weather', 'SNOW', 'SNWD'] # in this case, we are dropping rows with NaN values with the following columns
).shape
(293, 9)
```

#### **Trying Other Columns**

```
df_deduped.dropna(
how='all', subset=['TOBS', 'WESF']
).shape

(251, 9)
```

### This can also be performed along columns, and we can also require a certain number of null values before we drop the data

```
df_deduped.dropna(axis='columns', thresh=df_deduped.shape[0]*.75).columns
```

#### We can choose to fill in the null values instead with fillna() link text

 $df_{deduped.loc[:,'WESF'].fillna(0, inplace=True)}$  # we are locating the WESF column and filling the NaN values with 0  $df_{deduped.head()}$ 

	date	PRCP	SNOW	SNWD	TMAX	TMIN	TOBS	$\verb"inclement_weather"$	WESF	$\blacksquare$
1	2018-01-01T00:00:00	0.0	0.0	-inf	5505.0	-40.0	NaN	NaN	0.0	11.

#### Trying to fill other columns with another value

```
df_deduped.loc[:,'TOBS'].fillna(-15, inplace=True)
df_deduped.head()
#the NaN values in the TOBS column is now replaced with -15
```

-	WESF	$\verb"inclement_weather"$	TOBS	TMIN	TMAX	SNWD	SNOW	PRCP	date	
	0.0	NaN	-15.0	-40.0	5505.0	-inf	0.0	0.0	2018-01-01T00:00:00	1
	0.0	False	-12.2	-16.1	-8.3	-inf	0.0	0.0	2018-01-02T00:00:00	3
	0.0	False	-13.3	-13.9	-4.4	-inf	0.0	0.0	2018-01-03T00:00:00	6
	19.3	True	-15.0	-40.0	5505.0	inf	229.0	20.6	2018-01-04T00:00:00	8
	0.0	True	-13.9	-13.9	-4.4	inf	127.0	14.2	2018-01-05T00:00:00	11

At this point we have done every we can without distorting the data. We know that we are missing dates, but if we reindex, we don't know how to fill in the NaN data. With the weather data, we can't assume because it snowed one day that it will snow the next or that the temperature will be the same. For this reason, note that the next few examples are just for illustrative purposes only—just because we can do something doesn't mean we should. That being said, let's try to address some of remaining issues with the temperature data. We know that when TMAX is the temperature of the Sun, it must be because there was no measured value, so let's replace it with NaN and then we will make an assumption that the temperature won't change drastically day-to-day. Note that this is actually a big assumption, but it will allow us to understand how fillna() works when we provide a strategy through the method parameter. We will also do this for TMIN which currently uses -40°C for its placeholder when we know that the coldest temperature ever recorded in NYC was -15°F (-26.1°C) on February 9, 1934.ln [23]: df\_deduped.dropna( how='all', subset=['inclement\_weather', 'SNOW', 'SNWD']).shapeOut[23]:ln [24]: df\_deduped.dropna(axis='columns', thresh=df\_deduped.shape[0]\*.75).columnsOut[24]:ln [25]: df\_deduped.loc[:,'WESF'].fillna(0, inplace=True) df\_deduped.head()Out[25]:

The fillna() method gives us 2 options for the method parameter:

- 'ffill' to forward fill
- 'bfill' to back fill

```
df_deduped.assign(
TMAX=lambda x: x.TMAX.replace(5505, np.nan).fillna(method='ffill'),
TMIN=lambda x: x.TMIN.replace(-40, np.nan).fillna(method='ffill')
).head()
# The TOBS Column did not become NaN since we have tried to fill it with non NaN values in the previous cell
```

```

We can couple fillna() with other types of calculations for interpolation. Here we replace missing values of TMAX with the median of all TMAX values, TMIN with the median of all TMIN values, and TOBS to the average of the TMAX and TMIN values. Since we place TOBS last, we have access to the imputed values for TMIN and TMAX in the calculation. WARNING: the text has a typo and fills in TMAX with TMIN's median, the below is correct.

```
df deduped.assign(
TMAX=lambda x: x.TMAX.replace(5505, np.nan).fillna(x.TMAX.median()),
TMIN=lambda x: x.TMIN.replace(-40, np.nan).fillna(x.TMIN.median()),
# average of TMAX and TMIN
TOBS=lambda x: x.TOBS.fillna((x.TMAX + x.TMIN) / 2)
).head()
                                     SNOW SNWD TMAX TMIN TOBS inclement weather
                                                                                         WESF
                                                                                                 \blacksquare

We can also use apply() for running the same calculation across columns. For example, let's fill all missing values with their rolling 7 day median of their values, setting the number of periods required for the calculation to 0 to ensure we don't introduce more extra NaN values. (Rolling calculations will be covered in chapter 4.) We need to set the date column as the index so apply() doesn't try to take the rolling 7 day median of the date

0.0 -15.0

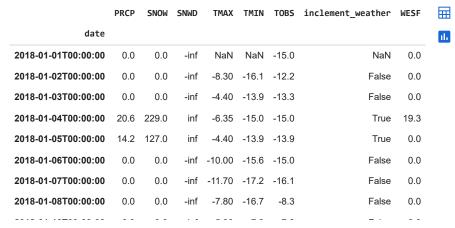

-4.4 -13.9 -13.9

```
df_deduped.assign(

TMAX=lambda x: x.TMAX.replace(5505, np.nan),

TMIN=lambda x: x.TMIN.replace(-40, np.nan)
).set_index('date').apply(

lambda x: x.fillna(x.rolling(7, min_periods=0).median())
).head(10)
```

The last strategy we could try is interpolation with the interpolate() method. We specify the method parameter with the interpolation strategy to use. There are many options, but we will stick with the default of 'linear', which will treat values as evenly spaced and place missing values in the middle of existing ones. We have some missing data, so we will reindex first. Look at January 9th, which we didn't have before—the values for TMAX, TMIN, and TOBS are the average of values the day prior (January 8th) and the day after (January 10th)

```
df_deduped.assign(

TMAX=lambda x: x.TMAX.replace(5505, np.nan),

TMTN=lambda x: x.TMIN.replace(-40, np.nan),
date=lambda x: pd.to_datetime(x.date)
).set_index('date').reindex(
pd.date_range('2018-01-01', '2018-12-31', freq='D')
).apply(
lambda x: x.interpolate()
).head(10)
```
